

PROBABILITY PROBLEM SOLVING – INDEPENDENT EVENTS

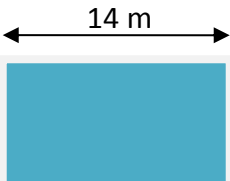

If A and B are **independent events** then:

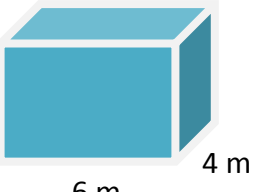

$$P(A \text{ and } B) = P(A) \times P(B)$$

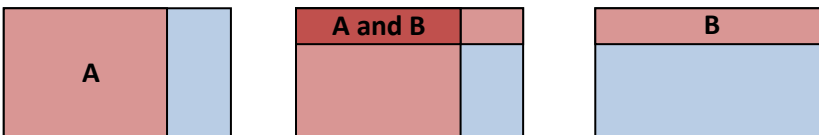

P1.  Calculate the probability of a fish being in regions A **and** B at the same time.

$P(A) = \frac{3}{5}$ $P(B) = \frac{4}{9}$?

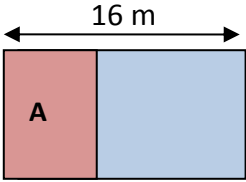

P2.  Calculate the probability of a fish being in the right-hand side of the tank **and** less than 2 metres from the surface.

P3.  Calculate the probability of a fish being in the bottom $\frac{2}{5}$ of the tank whilst being less than 3m from the left hand side.

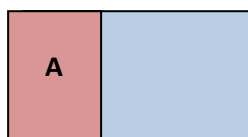

P4.  Calculate the probability of a fish being less than 2m from the surface whilst on the left-hand side and less than 1m from the front.

P5.  Calculate the probability of a fish being anywhere in region B.

$P(A) = \frac{4}{5}$ $P(A \text{ and } B) = \frac{4}{9}$

P6.  $P(A) = \frac{2}{5}$
Calculate the length x.

CHALLENGE

 $P(A) = \frac{5}{9}$
Calculate the length x.

How confident do I feel about independent event problems?
